Helt centralt for enhver diskussion ved morgenkonferencen!

Definition

CONFIRMATORY CRITERIAS

- Pussivning fra huddefekt eller tilstedeværelse af pus under operation
- Velkendte "positive mirror sign"
- Sårnedbrud med kommunikation til fremmedlegeme eller knogle
- Mikrobiologisk fund med to positive dyrkninger fra separate prøver
- Histopatologisk identifikation af svampe eller bakterier

Selv få bakterier kan gøre stor skade...

- Study from 1956.
- Injected 7,500,000 CFU *S. aureus* in skin of human volunteers = only 50% infected, all resolved
- < 100 CFU onto an implant in humans = 100% infected, did not resolve

EXPERIMENTAL STAPHYLOCOCCAL INFECTIONS
IN THE SKIN OF MAN

By Stephen D. Elek

St. George's Hospital Medical School, University of London, London, England

The concept of virulence of a microbe is relative to a given host species. The fact that an organism is capable of setting up lesions in experimental animal cannot be used as a basis for comparing the virulence of microbial strains in relation to another species of host. The traditional approach of using any convenient laboratory animal in virulence studies may yield completely fallacious findings if different metabolic products in other species of animals contribute to varying degrees of virulence in those species. There is evidence that the virulence of coagulase positive staphylococci does vary when tested on rabbits, mice, or other animals, but there is no information concerning the existence of similar differences in man (Frappier et al., 1955).

The carrier rate of coagulase-positive staphylococci and their distribution in dust, clothing, and elsewhere is very high, but clinical staphylococcal infection in man is comparatively rare. This suggests that either a minority of nasal strains are endowed with special virulence or that the circumstances of the infection determine the occurrence of disease. Since virulence testing on animals could not be expected to provide the correct answer, it was decided to compare a number of nasal strains with staphylococci isolated from human lesions by injecting volunteers intradermally. All the strains tested were coagulase-positive but, as the other biological properties of such material have frequently been described, no further details were regarded as relevant. Virulence testing in man being necessarily restricted in extent, our primary aim was to establish, within the limitations of the approach, whether or not differences in the resulting lesions could be demonstrated between randomly selected nasal strains of *Staphylococcus pyogenes* and other strains obtained from human lesions, and therefore presumed to be virulent. The indicator effect chosen was pus formation. Since staphylococci typically produce parafollicular lesions, the minimum inoculum surviving and progressing to pus formation can be used as the basis of comparison between the virulence to man of different strains.

Experiments on man with *Staph. pyogenes* have been carried out before (Garé, 1885; Bunn, 1885; and Bockhart, 1887), but only to show that they cause disease. No information was available concerning the minimum pus-forming dose or concerning differences between strains. Since the number of volunteers available was insufficient to test an adequate number of strains with different sizes of inocula it was decided to determine the minimal pus-forming dose for a strain freshly isolated from a severe lesion and then to compare the effects of the same dose of nasal and of some further known pyogenic strains. If the hypothesis that only a minority of nasal strains are virulent is correct, these strains would be expected not to cause pus formation at that dose.

A strain obtained from an abscess of the neck was injected in varying dilu-

Hvordan var det nu med aktuelle case...?

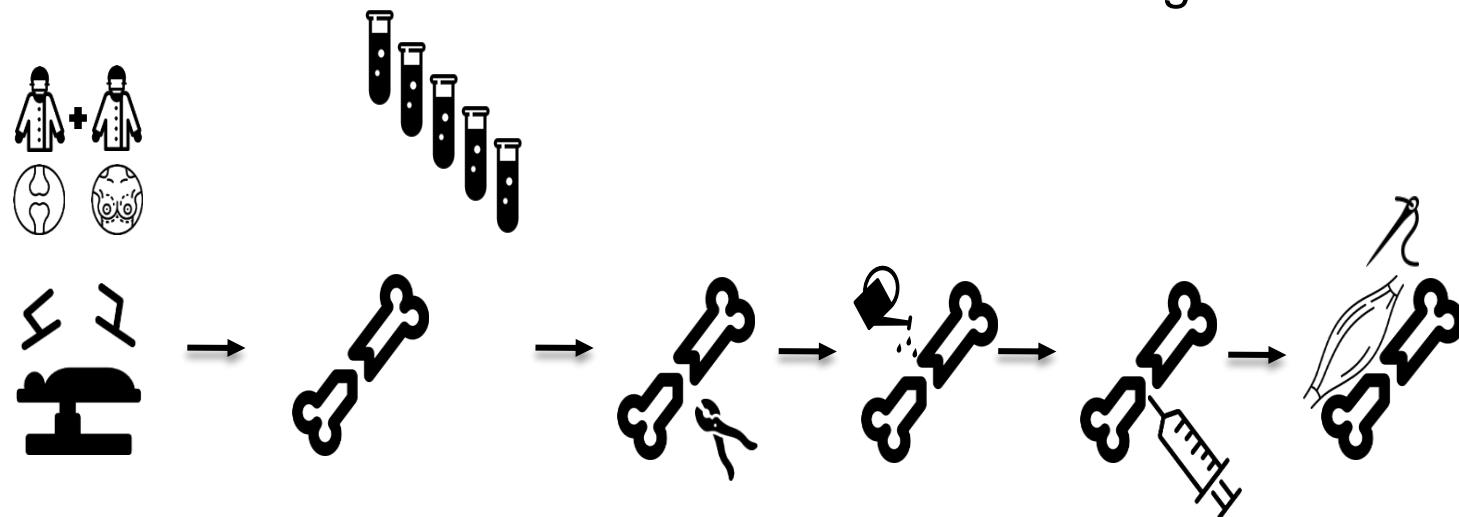

Infektion?

Behandling

One-stage-surgery

- á la Oxford

- Fjerne fremmedlegemer
- Prøvetagning
- Revision af inficeret knogle
- Skylle med saltvand
- Intraossøst "bone void filler" med antibiotika
- Primær lukning af bløddede

Behandling

Antibiotikabehandling

- Efter revision
 - Empirisk IV AB:
Dicloxacillin 1g x 4
Benzylpenicillin 2 MIE x 4
 - AB optimeret efter D+R
 - Én uges IV og 5 ugers tablet – OVIVA trial
 - Pt. kontrolleres i ambulatoriet
 - Optimere øvrige medicinske lidelser...
