Continuous Near-Infrared Spectroscopy
Demonstrates Limitations in Monitoring the
Development of Acute Compartment Syndrome in
Patients with Leg Injuries

Andrew H. Schmidt, MD, Michael J. Bosse, MD, William T. Obremsky, MD, MPH, Robert V. O'Toole, MD,
Eben A. Carroll, MD, Daniel J. Stinner, MD, David J. Hak, MD, Madhar Karunakar, MD, Roman Hayda, MD,
Katherine P. Frey, RN, MS, MPH, PhD, Junru Di, MS, Vadim Zilbermanik, PhD, Ellen MacKenzie, PhD, and
the Major Extremity Trauma Research Consortium (METRC)*

Results: For the original cohort, clinically useful NIRS data were available a median of 9.1% of the expected time, while IMP data were captured a median of 87.6% of the expected time ($p < 0.001$). Excluding 46 patients who had erroneous NIRS data recorded, the median percentage was 31.6% for NIRS compared with 87.4% for IMP data ($p < 0.00001$). Fractures with an associated hematoma were less likely to have valid data points (odds ratio [OR], 0.53; $p = 0.04$). Gustilo types I and II open fractures were more likely than Tscherne grades C0 and C1 closed fractures to have valid data points (OR, 1.97; $p = 0.03$).

Conclusions: In this study, NIRS data were not collected reliably. In contrast, IMP measurements were collected during >85% of the expected monitoring period. These data raise questions about the utility of current NIRS data capture technology for monitoring oxygenation in patients at risk of ACS.

Can intramuscular glucose levels diagnose compartment syndrome?

Christopher J. Doro, MD, Thomas J. Sitzman, MD, and Robert V. O'Toole, MD, Madison, Wisconsin

RESULTS: Within 15 minutes of creating compartment syndrome, glucose concentration and oxygen tension in the experimental limb were significantly lower than in the control limb (glucose, $p = 0.02$; oxygen, $p = 0.007$; two-tailed t test). Intramuscular glucose concentration of less than 97 mg/dL was 100% sensitive (95% confidence interval [CI], 73–100%) and 75% specific (95% CI, 40–94%) for the presence of compartment syndrome. Partial pressure of oxygen less than 30 mm Hg was 100% sensitive (95% CI, 72–100%) and 100% specific (95% CI, 69–100%) for the presence of compartment syndrome. Pathology confirmed compartment syndrome in all experimental limbs.

CONCLUSION: Our results show that intramuscular glucose concentration and partial pressure of oxygen rapidly identify muscle ischemia with high sensitivity and specificity after experimentally created compartment syndrome in this animal model. *U Trauma Acute Care Surg*.

Muscle Microvascular Blood Flow, Oxygenation, pH, and Perfusion Pressure Decrease in Simulated Acute Compartment Syndrome

Sraya T. Challa, BS, Alan R. Hargens, PhD*, Amarachi Uzosike, and Brandon R. Macias, PhD*

Investigation performed at the Department of Orthopaedic Surgery, UC San Diego Medical Center, University of California, San Diego, San Diego, California

Results: As IMP increased, muscle microvascular blood flow ($p = 0.01$), oxygenation ($p < 0.001$), and pH ($p < 0.001$) all decreased significantly in the experimental leg compared with the control leg. At all IMP levels, leg elevation significantly decreased muscle oxygenation ($p = 0.013$) and perfusion pressure ($p = 0.03$) compared with the control leg at heart level.

Conclusions: These results indicate that muscle microvascular blood flow, oxygenation, pH, and perfusion pressure decrease significantly as IMP increases in a human model of ACS.

Clinical Relevance: This study identifies hemodynamic and metabolic parameters as potential noninvasive diagnostic tools for ACS.

TABLE 1 Comparison of available diagnostic methods.

Method	Invasive	Continuous	Advantages	Disadvantages
IMP (Intramuscular Pressure)	Yes	Yes	Accurate, verified	Painful for the patient, risk of infection
Quantitative Hardness	No	No	Simple use	Low specificity, affected by the amount of subcutaneous fat
NIRS (Near Infrared Spectroscopy)	No	Yes	Simple and continuous monitoring	Depth max. 3 cm, unreliability of data acquisition, requires measurement on the control compartment, affected by pigment, skin damage, hematomas
SE (Strain Elastography)	No	No	Allows imaging of the compartment - it is not affected by hematomas and subcutaneous fat	Has not been validated in patients with ECS
SWE (Shear Wave Elastography)	No	No	Allows direct measurement of tissue stiffness	Not verified in patients with ECS, expensive, poor repeatability of measurements
PPLL (Pulsed Phase-Locked Loop)	No	Yes	Simple and continuous monitoring	Has not been verified in patients with ECS, may be affected by low blood pressure
Bioimpedance	No	Yes	Simple and continuous monitoring	Few studies performed, requiring control contralateral compartment

The Estimated Sensitivity and Specificity of Compartment Pressure Monitoring for Acute Compartment Syndrome

Margaret M. McQueen, MD, FRCSEd(Orth), Andrew D. Duckworth, MSc, MRCSEd, Stuart A. Aitken, MRCSEd,
and Charles M. Court-Brown, MD, FRCSEd(Orth)

Investigation performed at the Edinburgh Orthopaedic Trauma Unit, Royal Infirmary of Edinburgh, Edinburgh, Scotland

With the currently available evidence, the clinical diagnosis of acute compartment syndrome should no longer be considered the gold standard and we believe that all patients with tibial fractures who are at risk for acute compartment syndrome should undergo continuous intracompartmental pressure monitoring.

Årsag

Procentdel af patienter med kompartment (%)

The effect of early versus late fasciotomy in the management of extremity trauma

Arthur B. Williams, MD, Fred A. Luchette, MD, Harry T. Papaconstantinou, MD, Edward Li
James M. Hurst, MD, Jay A. Johannigman, MD, and Kenneth Davis, Jr., MD, Cincinnati, Ohio

Surgery
1997

- Fasciotomo mest effektiv når den udføres tidligt
- MEN, når udført sent:
 - Samme chance for at redde benet sammenlignet med tidlig fasciotomi
 - MEN øget risiko for infektion
- Resultaterne støtter aggressiv brug af fasciotomi uanset tidspunkt for diagnose
